

Assignment 3

Evan Curry Wilbur

March 5, 2023

2.2.2

Each of the following polynomials is written with its monomials ordered according to (exactly) one of lex, grlex, or grevlex order. Determine which monomial order was used in each case.

- a. $f(x, y, z) = 7x^2y^4z - 2xy^6 + x^2y^2$
- b. $f(x, y, z) = xy^3z + xy^2z^2 + x^2z^3$
- c. $f(x, y, z) = x^4y^5z + 2x^3y^2z - 4xy^2z^4$

Solution.

- a. grlex
- b. grevlex
- c. lex

□

2.2.3

Rewrite each of the following polynomials, ordering the terms using the lex order, the grlex order, and the grevlex order, giving $\text{LM}(f)$, $\text{LT}(f)$, and $\text{multideg}(f)$ in each case when the variables are ordered $z > y > x$

- a. $f(x, y, z) = 2x + 3y + z + x^2 - z^2 + x^3$
- b. $f(x, y, z) = 2x^2y^8 - 3x^5yz^4 + xyz^3 - xy^4$

Solution.

Before we start I just want to say I *despise* questions that are just applications of definitions like this.

a.

	Lex	Grlex	Grevlex
Polynomial	$-z^2 + z + 3y + x^3 + x^2 + 2x$	$x^3 - z^2 + x^2 + z + 3y + 2x$	$x^3 + x^2 - z^2 + 2x + 3y + z$
LM(f)	z^2	x^3	x^3
LT(f)	$-z^2$	x^3	x^3
multideg(f)	$(0, 0, 2)$	$(3, 0, 0)$	x^3

b.

	Lex	Grlex	C
Polynomial	$-3x^5yz^4 + 2x^2y^8 - xy^4 + xyz^3$	$2x^2y^8 - 3x^5yz^4 - xy^4 + xyz^3$	$2x^2y^8 - 3x^5yz^4 + xyz^3$
LM(f)	x^5yz^4	x^2y^8	
LT(f)	$-3x^5yz^4$	$2x^2y^8$	
multideg(f)	$(5, 1, 4)$	$(2, 8, 0)$	

□

2.2.5

Show that grevlex is a monomial order according to Definition 1.

Solution.

First we show that grevlex is total. Indeed, given $\alpha, \beta \in \mathbb{Z}_{\geq 0}^n$, without loss of generality if $|\alpha| < |\beta|$ then we are done. Otherwise $|\alpha| = |\beta|$. By definition, in $\alpha - \beta$, if there is no rightmost nonzero entry then $\alpha =_{\text{grevlex}} \beta$. If the rightmost nonzero entry is positive then $\alpha <_{\text{grevlex}} \beta$. If the rightmost nonzero entry is negative then $\alpha >_{\text{grevlex}} \beta$. One of these three must hold so the ordering is total.

Next we show that given $\alpha, \beta, \gamma \in \mathbb{Z}_{\geq 0}^n$, if $\alpha <_{\text{grevlex}} \beta$ then $\alpha + \gamma <_{\text{grevlex}} \beta + \gamma$. With this assumption, either $|\alpha| < |\beta|$ or $|\alpha| = |\beta|$. If $|\alpha| < |\beta|$ then since $|\alpha| + |\gamma| = |\alpha + \gamma|$ it follows that $|\alpha + \gamma| < |\beta + \gamma|$. So instead assume that $|\alpha| = |\beta|$. Let j be the rightmost nonzero index of $\alpha - \beta$. Since $\alpha <_{\text{grevlex}} \beta$, it must be that $\alpha_j - \beta_j > 0$ by definition of grevlex. Additionally, $\alpha_k - \beta_k = 0$ for all $j < k \leq n$. But then

$$\begin{aligned}
0 &= \alpha_k - \beta_k & k &= j+1, \dots, n \\
&= \alpha_k - \beta_k + (\gamma_k - \gamma_k) \\
&= (\alpha_k + \gamma_k) - (\beta_k + \gamma_k).
\end{aligned}$$

And also

$$\begin{aligned}
0 &< \alpha_j - \beta_j = \alpha_k - \beta_k + (\gamma_k - \gamma_k) \\
&= (\alpha_k + \gamma_k) - (\beta_k + \gamma_k)
\end{aligned}$$

which shows exactly what needed to be shown.

Now we finish this off by showing that it is well ordered. Given some $A \subseteq \mathbb{Z}_{\geq 0}^n$

we must demonstrate that this set has a minimal element. First, consider the mapping $f : \mathbb{Z}_{\geq 0}^n \rightarrow \mathbb{Z}_{\geq 0}$ by

$$(\alpha_1, \dots, \alpha_n) \mapsto \sum_{i=1}^n \alpha_i.$$

Notice that if $f(\alpha) < f(\beta)$ then it must be the case that $\alpha <_{\text{grevlex}} \beta$ since this is just mapping each monomial to its total degree. Since $\mathbb{Z}_{\geq 0}$ is well-ordered, $f(A)$ has a smallest element which we will call w . Observe that if A is to have a smallest element (thereby being a well-ordered set), such element must be in $f^{-1}(w) \cap A$ since this is just the set of elements of A with total degree w which must be the smallest degree found in A . We will now prove that $f^{-1}(w)$ is finite, hence $f^{-1}(w) \cap A$ is finite, and hence $f^{-1}(w) \cap A$ must contain a smallest element. Indeed, every element of $f^{-1}(w)$ is just an n -tuple whose elements sum to w . But this would mean that it's just a subset of the total partitions of w including all possible permutations. But we know that the partitions of any nonnegative number with nonnegative values must be finite, thus expanding that set with all possible permutations must also be finite, hence $f^{-1}(w)$ is finite. Therefore A has a smallest element and grevlex is well ordered. \square

2.2.6

Another monomial order is the **inverse lexicographic** or **invlex** order defined by the following: for $\alpha, \beta \in \mathbb{Z}_{\geq 0}^n$, $\alpha >_{\text{invlex}} \beta$ if and only if the rightmost nonzero entry of $\alpha - \beta$ is positive. Show that invlex is equivalent to the lex order with the variables permuted in a certain way. (Which permutation?)

Solution.

Lemma 1. *Let (S, \leq) and (T, \preceq) be two partial orders and $f : S \rightarrow T$ be an order embedding such that for all $\alpha, \beta \in S$, $f(\alpha + \beta) = f(\alpha) + f(\beta)$. Then if T is a monomial ordering, so is S .*

Proof. Let the above be given and suppose T is a monomial ordering. First, we show that (S, \leq) is a total ordering. Indeed, given some $\alpha, \beta \in S$, since (T, \preceq) is total, one and only one of the following must be true

1. $f(\alpha) < f(\beta)$
2. $f(\alpha) > f(\beta)$
3. $f(\alpha) = f(\beta)$.

In any of these three cases, by definition of an order embedding, the corresponding relation must be true. That is to say, if $f(\alpha) < f(\beta)$ then it must be the case that $\alpha < \beta$, and correspondingly for the remaining two possibilities. Thus S is totally ordered.

Next, we show that S is well-ordered. Let $A \subseteq S$ be some non-empty subset. Since $f(A) \subseteq T$ and T is well ordered, there must exist a smallest element $t \in f(A)$. Necessarily, since every order embedding is injective, there must exist a unique element $a \in A$ such that $f(a) = t$. It will be shown that a is the smallest element of A . Indeed if there were to exist some $a' \in A$ such that $a' < a$ then $f(a') < f(a) = t$, contradicting the fact that t is the smallest element of $f(A)$. Hence (S, \leq) is well-ordered.

Finally, we show that if $\alpha, \beta, \gamma \in A$ with $\alpha > \beta$ then $\alpha + \gamma > \beta + \gamma$. Again by definition of an order embedding, we must have $f(\alpha) > f(\beta)$. Additionally, $f(\gamma) \in T$ and since T is a monomial ordering it follows that

$$\begin{aligned} f(\alpha) + f(\gamma) &> f(\beta) + f(\gamma) && \implies \\ f(\alpha + \gamma) &> f(\beta + \gamma) && \implies \\ \alpha + \gamma &> \beta + \gamma. \end{aligned}$$

Thus (S, \leq) is a monomial ordering. \square

The mapping $f : (\mathbb{Z}_{\geq 0}^n, <_{\text{invlex}}) \rightarrow (\mathbb{Z}_{\geq 0}^n, <_{\text{lex}})$ given by $(\alpha_1, \dots, \alpha_n) \mapsto (\alpha_n, \dots, \alpha_1)$ is an order embedding with the property that $f(x+y) = f(x)+f(y)$.

First we show that f is injective. Indeed, given $\alpha, \beta \in \mathbb{Z}_{\geq 0}^n$, suppose that $f(\alpha) = f(\beta)$. Then with $\alpha = (\alpha_1, \dots, \alpha_n)$ and $\beta = (\beta_1, \dots, \beta_n)$ we have

$$\alpha_n = \beta_n, \dots, \alpha_1 = \beta_1$$

so $\alpha = \beta$.

Next, we show that f preserves the order of $(\mathbb{Z}_{\geq 0}^n, <_{\text{invlex}})$. Indeed, given $\alpha, \beta \in \mathbb{Z}_{\geq 0}^n$ suppose that $\alpha <_{\text{invlex}} \beta$. Then by definition, the rightmost nonzero index of $\alpha - \beta$ is positive. Call this index j so we have

$$\begin{aligned} \alpha_k - \beta_k &= 0 && \text{for } j+1 \leq k \leq n \\ \alpha_j - \beta_j &> 0. \end{aligned}$$

So then the image of these two values is

$$\begin{aligned} f(\alpha) &= (a_n, \dots, a_j, \dots, \alpha_1) \\ f(\beta) &= (\beta_n, \dots, \beta_j, \dots, \beta_1). \end{aligned}$$

But the leftmost nonzero entry in the image is the same as the rightmost nonzero entry in the preimage. So it must be the case that $f(\alpha) <_{\text{invlex}} f(\beta)$. A similar argument shows the other direction, namely that $f(\alpha) < f(\beta) \implies \alpha < \beta$. So f is an order embedding.

All that is left to show is that $f(\alpha + \beta) = f(\alpha) + f(\beta)$. Indeed,

$$\begin{aligned} f(\alpha + \beta) &= f((\alpha_1, \dots, \alpha_n) + (\beta_1, \dots, \beta_n)) \\ &= f((\alpha_1 + \beta_1, \dots, \alpha_n + \beta_n)) \\ &= (\alpha_n + \beta_n, \dots, \alpha_1 + \beta_1) \\ &= (\alpha_n, \dots, \alpha_1) + (\beta_n, \dots, \beta_1) \\ &= f((\alpha_1, \dots, \alpha_n)) + f((\beta_1, \dots, \beta_n)). \end{aligned}$$

So by the above **Lemma 1**, it must be that invlex is a monomial order. The permutation can be seen in how f is defined, it is simply the reversal of all the elements. \square

2.3.5

We will study the division of $f = x^3 - x^2y - x^2z + x$ by $f_1 = x^2y - z$ and $f_2 = xy - 1$.

- a. Compute using grlex order:

$$\begin{aligned} r_1 &= \text{remainder of } f \text{ on division by } (f_1, f_2). \\ r_2 &= \text{remainder of } f \text{ on division by } (f_2, f_1). \end{aligned}$$

Your results should be *different*. Where in the division algorithm did the difference occur?

- b. Is $r = r_1 - r_2$ in the ideal $\langle f_1, f_2 \rangle$? If so, find an explicit expression $r = Af_1 + Bf_2$. If not, say why not.
- c. Compute the remainder of r on division by (f_1, f_2) . Why could you have predicted your answer before doing the division?
- d. Find another polynomial $g \in \langle f_1, f_2 \rangle$ such that the remainder on division of g by (f_1, f_2) is nonzero. Hint: $(xy + 1) \cdot f_2 = x^2y^2 - 1$, whereas $y \cdot f_1 = x^2y^2 - yz$
- e. Does the division algorithm give us a solution for the ideal membership problem for the ideal $\langle f_1, f_2 \rangle$? Explain your answer

Solution.

- a. On a separate sheet of paper, I computed the remainder to be

$$\begin{aligned} r_1 &= x^3 - x^2z + x - z \\ r_2 &= x^3 - x^2z \end{aligned}$$

- b. Yes

$$r = -(x^2y - z) - x(xy - 1)$$

- c. There is no need to compute the remainder since it must be $r = x - z$. This can be readily seen since neither $\text{LT}(f_1)$ or $\text{LT}(f_2)$ divide any of the terms in r .
- d. The polynomial $g = yz - 1 \in \langle f_1, f_2 \rangle$, but the remainder on division of g by (f_1, f_2) is -1 .
- e. No, even if a polynomial $g \in \langle f_1, f_2 \rangle$, it need not be the case that the remainder of g by (f_1, f_2) is zero.

□

2.3.9

The discussion around equation (2) of Chapter 1, §4 shows that every polynomial $f \in \mathbb{R}[x, y, z]$ can be written as

$$f = h_1(y - x^2) + h_2(z - x^3) + r,$$

where r is a polynomial in x alone and $\mathbf{V}(y - x^2, z - x^3)$ is the twisted cubic curve in \mathbb{R}^3 .

- a. Give a proof of this fact using the division algorithm. Hint: You need to specify carefully the monomial ordering to be used.
- b. Use the parametrization of the twisted cubic to show that $z^2 - x^4y$ vanishes at every point of the twisted cubic.
- c. Find an explicit representation

$$z^2 - x^4y = h_1(y - x^2) + h_2(z - x^3)$$

using the division algorithm.

Solution.

- a. *Proof.* Fix the monomial ordering to be $>_{\text{invlex}}$ which is defined in **2.2.6**. Observe that, under this ordering, $\text{LT}(y - x^2) = y$ and $\text{LT}(z - x^3) = z$. Given some $f \in \mathbb{R}[x, y, z]$, the division algorithm yields q_1, q_2 , and $r \in \mathbb{R}[x, y, z]$ such that

$$f = q_1(y - x^2) + q_2(z - x^3) + r.$$

We need to show that r is a polynomial in x alone. By the division algorithm, there are two possibilities for r . Either $r = 0$ or r is a linear combination, with coefficients in k , of monomials, none of which is divisible by any $\text{LT}(y - x^2), \text{LT}(z - x^3)$. In the first case, we may obviously express r as a polynomial in x alone as

$$r(x) = 0.$$

In the latter case, let's assume for contradiction (and without loss of generality!) that r is a polynomial of y as well. Well then at least one monomial of r has the variable y with exponent greater than 0. But this would imply that y divides that monomial. But this is a contradiction since the division algorithm guarantees that no monomial of r can be divisible by $\text{LT}(y - x^2) = y$. So it must be that r is a polynomial in x alone. \square

- b. The parametrization of the twisted cubic is

$$\begin{aligned}x(t) &= t \\y(t) &= t^2 \\z(t) &= t^3.\end{aligned}$$

Substituting these for the expression gives

$$\begin{aligned}z^2 - x^4y &= (t^3)^2 - (t)^4(t^2) \\&= t^6 - t^4t^2 \\&= t^6 - t^6 \\&= 0\end{aligned}$$

and so it vanishes at every point of the twisted cubic.

- c.

$$z^2 - x^4y = -x^4(y - x^2) + (z + x^3)(z - x^3)$$

\square

2.3.10

Let $V \subseteq \mathbb{R}^3$ be the curve parametrized by (t, t^m, t^n) , $n, m \geq 2$.

- Show that V is an affine variety.
- Adapt the ideas in Exercise 9 to determine $\mathbf{I}(V)$.

Solution.

- We show that V is the affine variety $V(x^m - y, x^n - z)$. Given some $(x_0, y_0, z_0) \in V$ we have

$$\begin{aligned}x_0 &= t \\y_0 &= t^m \\z_0 &= t^n\end{aligned}$$

for some $t \in \mathbb{R}$ by the definition of V . Substituting these into the expressions for the affine variety give

$$\begin{aligned} x_0^m - y_0 &= t^m - t^m \\ &= 0 \end{aligned}$$

and

$$\begin{aligned} x_0^n - z_0 &= t^n - t^n \\ &= 0. \end{aligned}$$

So the point is in the affine variety and therefore $V \subseteq V(x^m - y, x^n - z)$. For the other direction, pick some $(x_0, y_0, z_0) \in V(x^m - y, x^n - z)$. By definition

$$\begin{aligned} x_0^m &= y & \text{and} \\ x_0^n &= z. \end{aligned}$$

If we let $t = x_0$ then substituting t for x_0 in the expressions above give

$$\begin{aligned} y_0 &= t^m \\ z_0 &= t^n. \end{aligned}$$

But this is exactly the definition of the parametrization V . So $V(x^m - y, x^n - z) \subseteq V$. Hence $V = V(x^m - y, x^n - z)$ is an affine variety.

- b. We will show that $\langle x^m - y, x^n - z \rangle = \mathbf{I}(V(x^m - y, x^n - z))$. **Lemma 7** on page 34 of the textbook says that

$$\langle x^m - y, x^n - z \rangle \subseteq \mathbf{I}(V(x^m - y, x^n - z)),$$

so we only need to show the other inclusion. Fix the monomial ordering to be $>_{\text{invlex}}$ and take some $f \in \mathbf{I}(V(x^m - y, x^n - z))$. With the division algorithm we can write

$$f = q_1(x^m - y) + q_2(x^n - z) + r$$

for $q_1, q_2, r \in \mathbb{R}[x, y, z]$. We show that r is a polynomial in x alone. Indeed, if this weren't the case, just like in the previous exercise, one of the monomials of r would be divisible by y or z . But this contradicts the division algorithm theorem since the leading terms of $x^m - y$ and $x^n - z$ are y and z respectively. So it must be that $r \in \mathbb{R}[x]$. But then $f \in \langle x^m - y, x^n - z \rangle$

$$0 = f(t, t^m, t^n) = 0 + 0 + r(t)$$

for every t . But this implies that r is the zero polynomial. Therefore $f \in \langle x^m - y, x^n - z \rangle$ and $\langle x^m - y, x^n - z \rangle \supseteq \mathbf{I}(V(x^m - y, x^n - z))$. Therefore,

$$\langle x^m - y, x^n - z \rangle = \mathbf{I}(V(x^m - y, x^n - z)).$$

□

2.4.3

Let $I = \langle x^6, x^2y^3, xy^7 \rangle \subseteq k[x, y]$.

- In the (m, n) -plane, plot the set of exponent vectors (m, n) of monomials $x^m y^n$ appearing in elements of I .
- If we apply the division algorithm to an element $f \in k[x, y]$, using the generators of I as divisors, what terms can appear in the remainder?

Solution.

For part (b), the only terms that can appear in the remainder are linear combinations of monomials that are not in the ideal. Using **Lemma 2** on page 70 of the textbook, we can list every monomial not in the ideal:

$$A = \{x^m y^n \mid (m < 6 \wedge n < 3) \vee (m < 2 \wedge n < 7) \vee (m < 1)\}.$$

So any linear combination with coefficients in k of the elements in A will give a possible remainder. \square

2.4.4

Let $I \subseteq k[x, y]$ be the monomial ideal spanned over k by the monomials x^β corresponding to β in the shaded region shown at the top of the next page.

- Use the method given in the proof of Theorem 5 to find an ideal basis for I .
- Find a minimal basis for I in the sense of Proposition 7.

Solution.

- a. First, we find the projection to be $J = \langle x^3 \rangle$. Since we have $x^3 y^6 \in I$, then $m = 6$. So we get the following “slices”

$$\begin{aligned} J_0 = J_1 = J_2 = J_3 &= \langle x^6 \rangle \\ J_4 = J_5 &= \langle x^5 \rangle. \end{aligned}$$

So

$$I = \langle x^6, x^6 y, x^6 y^2, x^6 y^3, x^5 y^4, x^5 y^5, x^3 y^6 \rangle.$$

- b. Since the number of generators of I is relatively small, we can do this by hand (or just look at the picture provided!)

$$I = \langle x^6, x^5 y^4, x^3 y^6 \rangle.$$

□

2.4.9

Suppose we have the polynomial ring $k[x_1, \dots, x_n, y_1, \dots, y_m]$. Let us define a monomial order $>_{\text{mixed}}$ on this ring that mixes lex order for x_1, \dots, x_n , with grlex order for y_1, \dots, y_m . If we write monomials in the $n+m$ variables as $x^\alpha y^\beta$, where $\alpha \in \mathbb{Z}_{\geq 0}^n$ and $\beta \in \mathbb{Z}_{\geq 0}^m$, then we define

$$x^\alpha y^\beta >_{\text{mixed}} x^\gamma y^\delta \iff x^\alpha >_{\text{lex}} x^\gamma \text{ or } x^\alpha = x^\gamma \text{ and } y^\beta >_{\text{grlex}} y^\delta.$$

Use Corollary 6 to prove that $>_{\text{mixed}}$ is a monomial order. This is an example of what is called a *product order*. It is clear that many other monomial orders can be created by this method.

Solution.

Lemma 2. *If (A, \leq_A) and (B, \leq_B) are monomial orders, then $(A \times B, \leq_{A \times B})$ defined by*

$$\begin{aligned} (a_1, b_1) <_{A \times B} (a_2, b_2) &\iff a_1 <_A a_2 \text{ or } a_1 = a_2 \text{ and } b_1 <_B b_2 \\ (a_1, b_1) >_{A \times B} (a_2, b_2) &\iff a_1 >_A a_2 \text{ or } a_1 = a_2 \text{ and } b_1 >_B b_2 \\ (a_1, b_1) =_{A \times B} (a_2, b_2) &\iff a_1 = a_2 \text{ and } b_1 = b_2 \end{aligned}$$

with $(a_1, b_1), (a_2, b_2) \in A \times B$, is a monomial ordering.

Proof. First we show that the ordering is total. Indeed, given $(a_1, b_1), (a_2, b_2) \in A \times B$, since the orderings on A and B are total, without loss of generality either $a_1 <_A a_2$ or $a_1 =_A a_2$. If $a_1 <_A a_2$ then by definition $(a_1, b_1) <_{A \times B} (a_2, b_2)$. If $a_1 =_A a_2$ then again by the total ordering on B either $b_1 <_B b_2$, $b_1 >_B b_2$, or $b_1 =_B b_2$. In any of these three cases, the order will be decided entirely by the order of B . So no matter what, any two elements in $A \times B$ will be comparable.

Next we will show that $A \times B$ is well-ordered. Given some $C \subseteq A \times B$, consider the projection $\text{fst} : C \rightarrow A$. Since A is well ordered, the image of this projection has a smallest element, say $a \in A$. Now define $C' = \text{fst}^{-1}(a) \cap C \subseteq C$, which is minimal in the first element. Using the other projection, $\text{snd} : C \rightarrow B$, on C' gives a subset $\text{snd}(C') \subseteq B$. Since B is well ordered, $\text{snd}(C')$ has a smallest element, say $b \in B$. The element (a, b) is the smallest element of C . Indeed if this weren't the case, there must be an $C \ni (a', b') < (a, b)$. If $a' <_A a$ then a wouldn't have been the smallest element of $\text{fst}(C)$. Likewise if $b' <_B b$. So (a, b) is the smallest element and we have a well-ordering.

Finally, given $(a_1, b_1), (a_2, b_2), (a', b') \in A \times B$ suppose $(a_1, b_1) <_{A \times B} (a_2, b_2)$. We need to show that $(a_1, b_1) + (a', b') <_{A \times B} (a_2, b_2) + (a', b')$. There are two cases to consider: $a_1 <_A a_2$ or $a_1 =_A a_2$. If $a_1 <_A a_2$ then $a_1 + a' <_A a_2 + a'$ because A is a monomial ordering. So $(a_1, b_1) + (a', b') <_{A \times B} (a_2, b_2) + (a', b')$. Otherwise, $a_1 =_A a_2$. So it must be that $b_1 <_B b_2$. But again, B is a monomial ordering so $b_1 + b' <_B b_2 + b'$. Thus $(a_1, b_1) + (a', b') <_{A \times B} (a_2, b_2) + (a', b')$. \square

Consider the mapping $f : k[x_1, \dots, x_n, y_1, \dots, y_m] \rightarrow k[x_1, \dots, x_n] \times k[y_1, \dots, y_m]$ given by $x^\alpha y^\beta \mapsto (x^\alpha, y^\beta)$. It's clear that this is an order embedding. So we show that $f(x + y) = f(x) + f(y)$. Indeed,

$$\begin{aligned} &f((\alpha_1, \dots, \alpha_n, \beta_1, \dots, \beta_m) + (\alpha'_1, \dots, \alpha'_n, \beta'_1, \dots, \beta'_m)) \\ &= f((\alpha_1 + \alpha'_1, \dots, \alpha_n + \alpha'_n, \beta_1 + \beta'_1, \dots, \beta_m + \beta'_m)) \\ &= ((\alpha_1 + \alpha'_1, \dots, \alpha_n + \alpha'_n), (\beta_1 + \beta'_1, \dots, \beta_m + \beta'_m)) \\ &= ((\alpha_1, \dots, \alpha_n), (\beta_1, \dots, \beta_m)) + ((\alpha'_1, \dots, \alpha'_n), (\beta'_1, \dots, \beta'_m)) \\ &= f((\alpha_1, \dots, \alpha_n, \beta_1, \dots, \beta_m)) + f((\alpha'_1, \dots, \alpha'_n, \beta'_1, \dots, \beta'_m)) \end{aligned}$$

which is what was desired. So by **Lemma 1** and **Lemma 2** defined in this assignment, $>_{\text{mixed}}$ is a monomial order. \square

2.5.1

Let $I = \langle g_1, g_2, g_3 \rangle \subseteq \mathbb{R}[x, y, z]$, where $g_1 = xy^2 - xz + y$, $g_2 = xy - z^2$ and $g_3 = x - yz^4$. Using the lex order, give an example of $g \in I$ such that $\text{LT}(g) \notin \langle \text{LT}(g_1), \text{LT}(g_2), \text{LT}(g_3) \rangle$.

Solution.

Let $g = yz^4 - z^2$. Then $g \in I$ since

$$g = g_2 + yg_3.$$

But $\text{LT}(g) = yz^4 \notin \langle \text{LT}(g_1), \text{LT}(g_2), \text{LT}(g_3) \rangle$ since every element of $\langle \text{LT}(g_1), \text{LT}(g_2), \text{LT}(g_3) \rangle$ must have a nonzero power term for x , but none exist in $\text{LT}(g) = yz^4$. \square

2.5.7

If we use grlex order with $x > y > z$, is $\{x^4y^2 - z^5, x^3y^3 - 1, x^2y^4 - 2z\}$ a Gröbner basis for the ideal generated by these polynomials? Why or why not?

Solution.

Let $I = \langle x^4y^2 - z^5, x^3y^3 - 1, x^2y^4 - 2z \rangle$. The polynomial

$$2x^2z - z^5y^2 = y^2(x^4y^2 - z^5) - x^2(x^2y^4 - 2z) \in I.$$

So

$$\text{LT}(2x^2z - z^5y^2) = 2x^2z \in \langle \text{LT}(I) \rangle.$$

But with the leading terms

$$\text{LT}(x^4y^2 - z^5) = x^4y^2$$

$$\text{LT}(x^3y^3 - 1) = x^3y^3$$

$$\text{LT}(x^2y^4 - 2z) = x^2y^4,$$

it can be seen none of these divide $2x^2z$, so this combined with the division algorithm imply $2x^2z \notin \langle \text{LT}(x^4y^2 - z^5), \text{LT}(x^3y^3 - 1), \text{LT}(x^2y^4 - 2z) \rangle$ and hence it is not a Gröbner basis. \square

2.5.8

Repeat Exercise 7 for $I = \langle x - z^2, y - z^3 \rangle$ using the lex order. Hint: The difficult part of this exercise is to determine exactly which polynomials are in $\langle \text{LT}(I) \rangle$

Solution.

Let $G = \{x - z^2, y - z^3\}$. The **S-polynomial** for the two terms in G is

$$S(x - z^2, y - z^3) = \frac{xy}{x}(x - z^2) - \frac{xy}{y}(y - z^3) = xz^3 - yz^2.$$

Furthermore,

$$xz^3 - yz^2 = z^3(x - z^2) - z^2(y - z^3)$$

so by Buchberger's Criterion, G is a Gröbner basis of I . \square

2.5.9

Let $A = (a_{ij})$ be an $m \times n$ matrix with real entries in row echelon form and let $J \subseteq \mathbb{R}[x_1, \dots, x_n]$ be an ideal generated by the linear polynomials $\sum_{j=1}^n a_{ij}x_j$ for $1 \leq i \leq m$. Show that the given generators form a Gröbner basis for J with respect to a suitable lexicographic order. Hint: Order the variables corresponding to the leading 1's before the other variables

Solution.

Started working on this problem too late. Not enough time to finish it. Doing some research I was able to find this paper. I'm going to use the proposition to solve this. I'm willing to accept a loss of points for doing this. I just needed something for the answer here. So without further ado

First, define

$$\vec{x} = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}.$$

Now there will exist an $n \times n$ permutation matrix S such that the product $AS\vec{x}$ gives a vector whose entries are just the polynomials which generate the ideal J . Indeed, this just follows from how we are defining J as a linear combination of variables x_i . We may now define an order on the variables by the order they appear in the resulting vector product $S\vec{x}$. That is to say, we let the first entry in $S\vec{x}$ be greater than the second and so on. Observe also that $AS\vec{x}$ is just a vector whose entries are the generators of J so defined. Additionally, the order of the entries corresponds to the order of the generators given the ordering specified earlier.

There will exist a unique matrix R such that RA is in reduced row echelon form. Clearly in general, $RAS\vec{x} \neq AS\vec{x}$ however, this product preserves the order of the entries of the result and leading terms. That is to say, if we take the leading terms of $RAS\vec{x}$, it equals exactly the leading terms of $AS\vec{x}$. By the proposition, we have a matrix in reduced row echelon form so its nonzero rows precede its zero rows and its nonzero rows form a reduced Grobner basis for its row space.

I feel dirty for doing that, so sorry. I'll be sure to come into office hours so I can better understand this problem.
